EXPERIMENT – 10

Performance Optimization in Zoho Creator

Recruitment & Job Application Management

Particulars	Details
Student Name	Lalitha B
Roll Number	241401045
Department	Computer Science and Business Systems (CSBS)
Experiment Number	10
Platform	Zoho Creator
Application Name	Recruitment & Job Application Management

1. Aim

To demonstrate performance optimization in a Zoho Creator job application workflow by using criteria-based retrieval of the relevant application record, limiting unnecessary processing, and verifying that the job application acknowledgement email continues to work.

2. Introduction

Performance optimization in low-code platforms means reducing unnecessary data retrieval, repeated processing, and avoidable workflow operations. In recruitment systems, retrieving every application just to locate one candidate is less efficient than identifying the submitted application by its unique record ID.

3. Application Used

This experiment uses the existing **Recruitment & Job Application Management** application, its **Job application form**, and the **Send Job Application Confirmation Email** form workflow created in an earlier experiment.

4. Performance Optimization Concept

The central optimization is to retrieve only the current record using **ID == input.ID**, instead of fetching all submitted job applications and searching through them. The selected record can then be checked for an email address before generating the acknowledgement.

5. Procedure

Step 1 – Open the application

Open Zoho Creator, select Recruitment & Job Application Management, and enter the application builder.

Step 2 – Locate the form workflow

Go to Workflow → Form Workflows. Open Send Job Application Confirmation Email, which is associated with Created → Successful form submission.

Step 3 – Review the current Deluge action

Open the Deluge script action that sends an acknowledgement to the applicant. Preserve a copy of the working script before making changes.

Step 4 – Optimize record retrieval

Use the submitted record ID with the criteria **Job_application_form[ID == input.ID]**, confirming the exact form link name in the application. Check that the record and its Email field are available before sending email.

Step 5 – Save and test

Save or update the script, submit a new test job application, and verify that the confirmation message reaches the candidate email inbox.

Step 6 – Review the result

Compare the targeted retrieval approach with the conceptual alternative of fetching all applications. Record only outcomes actually observed.

6. Illustrative Optimized Deluge Logic

The following is the intended criteria-based retrieval pattern. The screenshots supplied for this report show the workflow and email receipt, but do not show the updated retrieval statement; therefore implementation of this particular optimization is not independently verified by the screenshots.

```
candidateRecord = Job_application_form[ID == input.ID];
if(candidateRecord.count() > 0)
{
    if(!candidateRecord.Email.isBlank())
    {
        sendmail
        [
            from : zoho.adminuserid
            to : candidateRecord.Email
            subject : "Job Application Received - Recruitment Team"
            message : "Your application has been received."
        ]
    }
}
```

7. Performance Analysis

Approach	Record retrieval and processing
Unoptimized (conceptual)	Fetch all applications, iterate through records, locate the current one, then process.
Optimized (proposed)	Fetch the current application by ID and process the relevant record only.

This comparison is conceptual. No execution-time benchmark was performed, and no numerical performance improvement is claimed.

8. Implementation Evidence

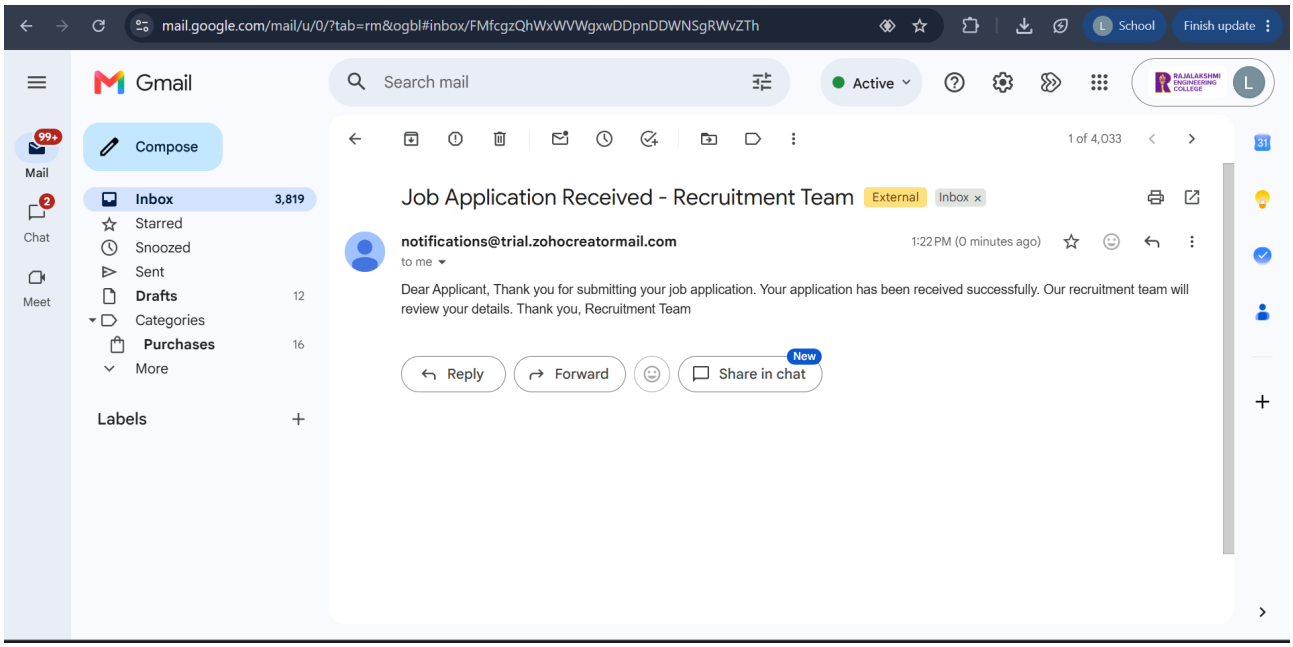

Figure 1. Existing Job Application Confirmation workflow configured for successful form submission, showing the Deluge action.

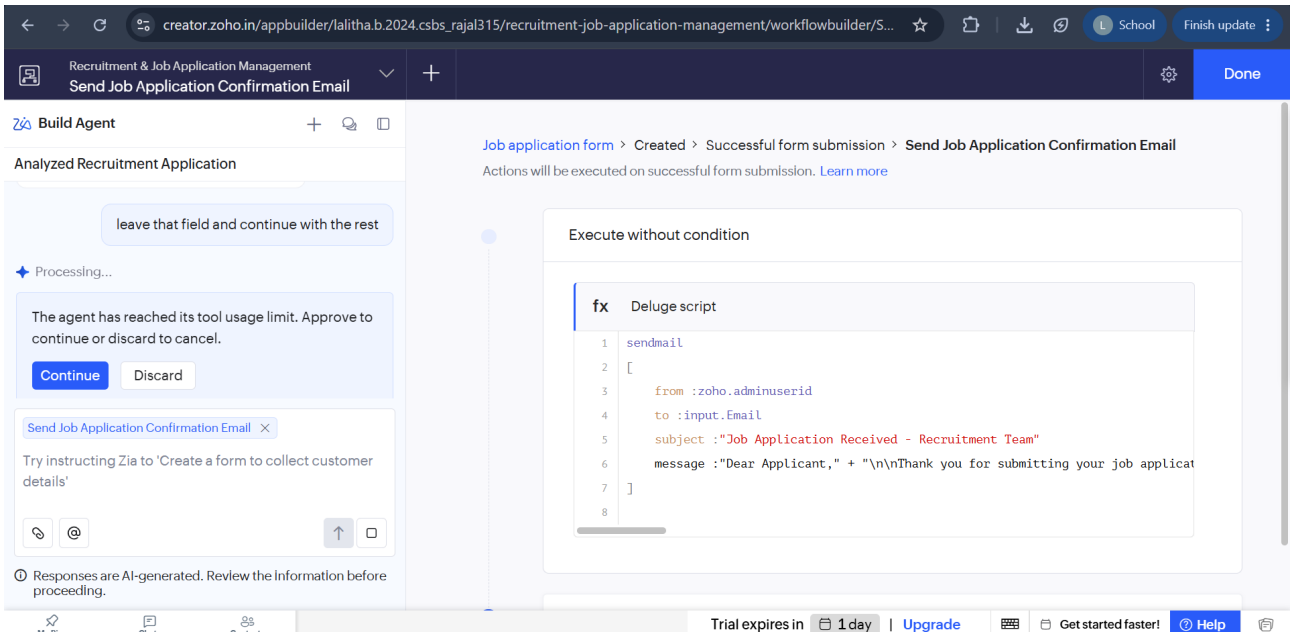

Figure 2. Confirmation email received in Gmail after a test job application submission.

9. Observations and Result

The screenshots confirm the presence of a job application confirmation workflow and receipt of an acknowledgement email. The targeted retrieval approach is documented as the intended optimization technique. Verification of the final optimized script would require a screenshot or inspection of the updated Deluge action.

10. Conclusion

This experiment illustrates why criteria-based record fetching and simple validation logic are useful in Zoho Creator workflows. Identifying the current job application by its unique ID avoids unnecessary retrieval of unrelated records. The email test verifies the acknowledgement workflow; execution-time gains and the final retrieval implementation have not been separately benchmarked or evidenced.
